 AB A novel modified alternan, produced by using newly isolated strains of Penicillium sp., was phys. characterized. High mol. weight native alternan was progressively modified to lower mol. weight heterodisperse forms, associated with a reduction in absorbance at 225 nm, light scattering, and opalescence. Methylation anal. indicated that modified alternan has a linkage pattern similar to that of native alternan. The solution viscosity properties of modified alternan resemble those of ultrasonicated alternan and com. gum arabic. However, alternan lacks the emulsification capacity of gum arabic. Alternan solns. are stable for at least 7 days under all conditions tested, from 4 to 70° and from pH 3-9. Dry preps. of alternan are bright white powders that are not highly hygroscopic. Thus, modified alternan is promising for further development as a gum arabic substitute, particularly in food applications requiring a low-viscosity bulking agent.

AB Four new *Penicillium* spp. isolates (NRRL 21966, NRRL 21967, NRRL 21968, and NRRL 21969) are capable of essentially quant. conversion of native alternan to a polymeric modified form having a lower apparent mol. weight than native alternan. A 5th isolate (NRRL 30489) obtained from a survey of deposited organisms and classified as a *Penicillium* subgenus *Biverticillium* has the same ability. The modified alternan has rheol. properties similar to ultrasonicated alternan and is produced without the expense of ultrasonication. It would have utility as a substitute for gum arabic for uses such as bulking agents and extenders in foods and cosmetics.

AB Alternan known as a kind of dextran is a linear and cyclic polysaccharide which is synthesized with sucrose by alternansucrase (EC 2.4.1.140) of *Leuconostoc mesenteroides*. But this polysaccharide is different from dextran in its structure and other properties. For the purpose of applying alternan for the food, cosmetic, and pharmaceutical industries, we isolated an excellent alternan-producing strain, *Leu. mesenteroides* CBI-110. The optimum culture conditions were studied to improve the yield, and the activity of alternansucrase was increased up to 33U/mL in the optimum culture media. The concns. of Mn²⁺ and Cu²⁺ ions were 0.01% and 0.03%, resp., for the effective production of alternan. Finally, we obtained 25.6 g/L of alternan.

AB A review with 70 refs. Alternan is an unusual microbial polysaccharide consisting of an alternating sequence of $\alpha(1\rightarrow3)$ and $\alpha(1\rightarrow6)$ -linked D-glucose units. Chemical related to dextran, it is produced from sucrose by a single extracellular enzyme from certain strains of the lactic-acid bacterium *Leuconostoc mesenteroides*. Because of its unusual linkage structure, alternan is resistant to many hydrolytic enzymes that degrade starch, dextran, and other α -D-glucans. The viscosity of alternan is relatively low compared with most food gums. These properties have caused us to consider alternan for a number of food -related applications, including use as a reduced-calorie bulking agent. This paper describes some recent work on the characterization and production of alternan, as well as some related work on highly branched limit dextrans.

AB The present invention relates to a method for manufacturing modified polysaccharides comprising placing the polysaccharide in contact with a sugar group-transferring enzyme and a sugar group donor. The placing of the polysaccharide in contact with a sugar group-transferring enzyme and a sugar group donor can be effected in vivo as well as in vitro. The result of the method is modified polysaccharides which can be used for different food and non-food applications. Examples include use of *Bacillus subtilis* gene *sacB* levan sucrase or *Leuconostoc mesenteroides* dextran sucrase. Enzymes produced in transgenic tobacco or potato chloroplasts result in altered starch granules and polysaccharide accumulation.

AB *Paphiopedilum villosum* was studied in hill evergreen forests (at up to 35 m above ground level) in North Thailand between 1990 and 1994. Flowering lasted 4.5 months: flower longevity 2-3 months. During 224 hours of flower-watching, less than 100 specimens of Syrphidae (Diptera) were seen in the vicinity of the flowers; 15 cases of pollen acquisition were mainly by female *Episyrphus alternans*, *Syrphus fulvifacies*, *Betajyrphus serarius* among 6 spp. of pollinators. Populations peaked during the main flower opening period, one month before the maximum number of open flowers was reached in early February. The flowers are 'kettle-traps' without known reward, luring mainly by food deception. Long distance attraction is probably by a urine-like odour (attraction to mammalian excretions had hitherto been little reported) and colour contrast. Close range lure is by the glittering staminode (probably mimicking droplets of honeydew/moisture) centered by a slippery wart (faking a perch) at which pollinators fly, immediately losing their grip and tumbling into the pouch, preventing wing action and falling being disrupted by a trough-shaped frame. Escape is up the tunnel, past the stigma, to the exit where, pressed by several mechanisms against the anther, the hoverfly scoops off very sticky pollen which has a viability of at least 8 weeks. Capsule formation averaged 8%.

AB Mycobiota was studied in the eggs, milt, muscles, and liver of sturgeons and sevryugas. The following species were identified: *Stachybotrys alternans*, *Cladosporium* sp., *C. herbarum*, *Curvularia* sp., *Stemphylium* sp., *Alternaria* sp., *A. alternata*, *Aspergillus carbonarius*,

Fusarium sp., F. gibbosum, Penicillium sp., P. chrysogenum, P. expansum and Rhizopus nigricans. Fusarium and Penicillium species predominated in 43 strains isolated (39% and 18.6% respectively). The spores of the fungi are able to accumulate in the fish. High salt resistance of these saprotrophic fungi results in the contamination of final fish food products.

AB In 1980, the presence of celery weevil (H. adspersa var. alternans) was established in Hokkaido, Japan. This weevil was known as a pest of celery crops in Europe and in 1 rare example it was reported as attacking alfalfa in Russia [USSR]. The species of hyperinuous weevil in Japan are distinguished by the scale form on elytra. In the case of celery weevil, lobation on the scale is of the smallest degree, and there are some small notches present within the lobation. The hind wings are very small and due to this fact it is almost impossible for the weevils to fly and become distributed. The weevil generally overwinters only in the adult stage. In spring, the weevils oviposit. Egg-laying last .apprx. 40 days, with 1 female laying 200-500 eggs. Incubation is 6 days at 20° C. The larvae feed on Umbelliferous plants for 10 days at 20° C. The pupal stage lasts 6 days. In Hokkaido, most the weevils left food plants in mid-Aug. There is probably only 1 generation of insects/yr.

AB Food preferences of 5 spp. of adult carabids, Scarites substriatus Haldeman Evarthrus alternans, Casey Pterostichus chalcites, Say, P. lucublandus Say and Harpalus pensylvanicus De Geer were investigated under laboratory conditions. Various plant and animal material, as well as detritus were tested. Dead black cutworm larvae were the most preferred food for all species tested. H.

pensylvanicus and *E. alternans* did, however, feed on a number of seeds. *H. pensylvanicus* may be quite omnivorous in its feeding habits. In general, dead crickets and both live and dead smooth-skinned Lepidoptera larvae were attractive food items, while isopods, phalangids, slugs and earthworms were not. *E. alternans*, *P. lucublandus* and *H. pensylvanicus* significantly preferred dead invertebrates over live ones. The attractiveness of dead animal material has special significance. The application of insecticides, which kill large numbers of insects, may be indirectly poisoning potential predators because of the carabid's willingness to feed on dead or dying insects.

AB Stachybotryotoxicosis in cattle is caused by straw and hay that is contaminated with the mold *Stachybotrys alternans*. Upon autopsy, large hemorrhages, ulcers (some dried), dried necrotic foci and degenerate areas, mycelia and *Mucor*-type fungi have been discovered. *S. alternans* did not grow in the internal organs, as determined by experimental infection and field studies. Development of lesions may be caused by secondary molds. The toxin *S. alternans* reduces the number of immunocompetent leukocytes, hindering the immunoreactions of the organism and the formation of immunoglobulins and thus immunosuppression. An immunosuppressive effect must be considered in regard to other fungal toxicosis. Facultative pathogenic microorganisms can cause mass diseases and death of animals fed with toxic food, and this is in consequence of an immunosuppressive effect. The active immunization (vaccination) of such animals is unsuccessful.

AB The following cerambycid beetles were reared in Honolulu from pruned-off
branches of the breadfruit tree, under circumstances indicating that their
life cycles were rather short, not more than 4 mos. Lagocheirus
obsoletus, Oopsis nutatdr, Pterolophia camura, Sybra alternans.
The larval period is apparently determined by the condition of the
food supply. As the larvae feed in the fermenting and decaying
outer wood, they must obtain their growth before these food
materials become too much dried up. They bore into the wood to form pupal
cells for final transformation. ABSTRACT AUTHORS: O. H. Swezey

AB C. fatigans is found associated with 9 species of mosquitoes in the Greater Brisbane area. The association is dependent largely on the state of the water at time of selection. There exist cyclic variations in the associations referred to, due to rain and atmospheric conditions, in which temperature and humidity play no small part. The study of pH throws no light on

the reason for selection, but only serves as an indication of the type of water preferred by certain kinds of foodstuffs, organisms, or aquatic vegetation. There is considerable mortality among the developmental stages of *C. fatigans* at all times, but especially during hot summer weather. Investigations into the breeding of mosquitoes in the Brisbane cemeteries lead to the belief that *C. fatigans* and *Aedes notoscriptus* choose the artificial receptacles on graves more than other mosquitoes; while *Aedes argenteus* prefers vessels near human habitations. *Mucidus alternans*, a cannibalistic species, and *Aedes* (0.) *vigilax*, usually associated with it, are both by nature saltwater marsh mosquitoes, but their presence at certain times of the year in large numbers in fresh waterholes is significant and highly undesirable. When these occur in association with *A. vittiger* it is interesting to note that, in spite of the fact that larvae of *A. vittiger* are predaceous, they will, nevertheless, avoid any intercourse with the other 2 mosquitoes even if found in the same water, and will select a secluded spot where they are less liable to attack. Observations show that the Charophyta referred to here, and which are comparatively common around Brisbane, do not thrive in pollution; hence, when mosquito larvae exist in conjunction with *Nitella* in the field, it is usually in the company of *A. annulipes* and with other sylvan mosquitoes rather than with *C. fatigans*. Under laboratory conditions, however, it is common for *C. fatigans* to lay egg-rafts on *Nitella* water, though *A. argenteus* selectively seems to do so more frequently. Though the presence of food seems to be the determining factor in the selection of breeding places by *C. fatigans*, the number and quality of decomposition products in the water may be said to be the main determining factors with regard to its measure of retardation in development. The possibilities of the septic tank and tannery pits as breeding grounds for *C. fatigans* must be recognized in any active anti-mosquito campaign. SUMMARY LANGUAGE: English

AB A novel method for the production of cyclic alternan tetrasaccharide makes use of readily available polysaccharides or oligosaccharides, particularly starch. The invention is based on the discovery that cyclic alternan tetrasaccharide may be produced by alternanase hydrolysis of complex carbohydrates other than alternan. The process can be performed using other substrates such as panose, which may be produced from polysaccharides or oligosaccharides, including starch, maltose, pullulan and their mixtures. The resulting product may be used as a metal salt complexing agent, a sucrose substitute, and as bulking agents in foods.

SUMMARY LANGUAGE: English

AB Alternan is a unique alpha-D-glucan soluble glucose-polysaccharide, in which alternating alpha-(1-6) and alpha-(1-3) linkages predominate in the polysaccharide backbone. Alternan and its low-molecular-weight derivatives have functional characteristics resembling gum arabic, maltodextrin or polydextrose, and have potential value as non-caloric, carbohydrate-based food additives in artificially sweetened foods. This invention describes a rapid screening procedure for selecting microorganisms that produce a high proportion of alternan to dextran, and a high proportion of alternan sucrose to dextran sucrose. Strains selected by the method can be used to produce alternan by cultivation of the strains on sucrose, or to produce alternansucrase, which can then be used to produce alternan from sucrose enzymically.

AB Consideration is given to the effects of simple and complex sugars, and food types on blood glucose levels; sugar-free bread; and bulking agents to replace sugar. The following bulking agents are briefly discussed: sugar alcohols - maltodextrins, polyols, hydrogenated starch hydrolysates, isomalt, lactitol, maltitol, mannitol, sorbitol and xylitol; and poorly digestible oligosaccharides - alternan, inulin and polydextrose. In addition, the digestibility and application of resistant starch (e.g. in bakery products) are addressed.

SUMMARY LANGUAGE: English

AB Owing to the lack of supply and the high cost of gum arabic, there is a need for a highly soluble, relatively low-viscosity alternative gum. There is also a need for reduced-calorie or non-caloric bulking agents and fillers for use in artificially sweetened foods. This paper investigated the properties of native alternan, which is an alternating alpha-D-glucan produced from sucrose by the extracellular enzyme system of a strain of *Leuconostoc mesenteroides*, and low-molecular-weight fractions of alternan. The authors conclude that glucan preparations may be of use as non-digestible, non-caloric, carbohydrate-based, soluble fillers and bulking agents in certain artificially sweetened food preparations and would have certain advantages over gum arabic and other, similar gums.

AB The production of an enzyme by *Leuconostoc mesenteroides*, which can split sugar into fructose and a long-chain polymer known as alternan, is currently under investigation by scientists. Alternan may be used as a cheap substitute for gum arabic, maltodextrins and other non-calorific food components. Technologies for the mass production of alternan are under development. Possible applications are suggested.
